DESCRIPTION

MP158 is a primary-side regulator that provides accurate constant voltage (CV) regulation without opto-coupler. It supports Buck, Buck-Boost, Boost and Flyback topologies. It has an integrated 500V MOSFET to simplify the structure and reduce costs. These features make it an ideal regulator for off-line low power applications, such as home appliances and standby power.

MP158 is a green-mode-operation regulator. Both the peak current and switching frequency decrease as the load decreases. This feature provides excellent efficiency at light load, thus improving the overall average efficiency.

MP158 features various protections, including thermal shutdown (TSD), VCC under-voltage lockout (UVLO), overload protection (OLP), short-circuit protection (SCP), and open loop protection.

MP158 is available in small TSOT23-5 package and SOIC8 package.

FEATURES

- Primary-side constant voltage (CV) control, supporting Buck, Buck-Boost, Boost and Flyback topologies
- Integrated 500V MOSFET and current source
- <30mW no-load power consumption
- Up to 2W output power
- Maximum DCM output current less than 40mA
- Maximum CCM output current less than 70mA
- Low VCC Operating Current
- Frequency foldback
- Limited maximum frequency
- Peak-current compression
- Internally biased VCC
- Thermal shutdown (auto restart)
- VCC under voltage lockout with hysteresis
- Timer based over-load protection.
- Short-circuit protection
- Open-loop protection

APPLICATIONS

- Home appliances, white goods and consumer electronics
- Industrial controls
- Standby power

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are Registered Trademarks of Monolithic Power Systems, Inc.

### Recommended Operating Conditions \(^{(3)}\)

- Operating Junction Temp. \(T_J\) | -40°C to +125°C
- Operating VCC range | 5.3V to 5.6V

### Thermal Resistance \(^{(4)}\)

| TSOT23-5 | 100 \(\) °C/W |
| SOIC-8 | 96 \(\) °C/W |

### Notes:

1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature \(T_J(MAX)\), the junction-to-ambient thermal resistance \(\theta_{JA}\), and the ambient temperature \(T_A\). The maximum allowance continuous power dissipation at any ambient temperature is calculated by

\[
PD(MAX) = \frac{T_J(MAX) - T_A}{\theta_{JA}}
\]

Exceeding the maximum allowance power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuit protects the device from permanent damage.

3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.
## ELECTRICAL CHARACTERISTICS

VCC = 5.8V, TJC=−40°C to 125°C, Min & Max are guaranteed by characterization, typical is tested under 25°C, unless otherwise specified.

Figure 1: Functional Block Diagram
OPERATION

MP158 is a green-mode-operation regulator: the peak current and the switching frequency both decrease with a decreasing load. As a result, it offers excellent light-load efficiency, and improves average efficiency. The typical application diagram shows the regulator operates with minimum external components. It incorporates multiple features as described in the following sections.

Start-Up and Under-Voltage Lockout

The internal high-voltage regulator self-supplies the IC from Drain pin. When VCC voltage reaches 5.6V, the IC starts switching and the internal high voltage regulator turns off. The internal high-voltage regulator turns on to charge the external VCC capacitor when the VCC voltage falls below 5.3V. A small capacitor (in the low μF range) can maintain the VCC voltage and thus lower the capacitor cost.

The IC stops operation when VCC voltage drops blow 3.4V.

Under fault conditions—such as OLP, SCP, and OTP—the IC stops switching and an internal current source (~16μA) discharges the VCC capacitor. The internal high-voltage regulator will not charge the VCC capacitor until the VCC voltage drops below 2.4V. The restart time can be estimated using the following equation,

\[ \tau_{\text{restart}} = C_{\text{VCC}} \times \frac{V_{\text{CC}} - 2.4V}{16\mu A} + C_{\text{VCC}} \times \frac{5.6V - 2.4V}{3.5mA} \]

Figure 2 shows the typical waveforms with VCC under-voltage lockout.

Soft-Start

The IC stops operation when VCC voltage drops blow 3.4V and starts operation when VCC charges to 5.6V. Every time when the chip starts operation there is a Soft-Start period. The soft-start prevents the inductor current from overshooting by limiting the minimum off time.

MP158 adopts a 2 phase minimum off-time limit soft-start. Each soft-start phase retains 128 switching cycles. During soft-start, off-time limit gradually shortens from 72μs to 22.5μs and finally to the 9μs normal operation off-time limit (see Figure 3).

Figure 3: \( \tau_{\text{minoff}} \) at Start-Up

Constant Voltage Operation

MP158 acts as a fully-integrated regulator when used in the Buck topology, as shown in the typical application on page1.

It regulates the output voltage by monitoring the sampling capacitor.

At the beginning of each cycle, the integrated MOSFET turns on while the feedback voltage drops below the 2.55V reference voltage, which indicates insufficient output voltage. The peak current limitation determines the ON period. After the ON period elapses, the integrated MOSFET turns off. Sampling capacitor (C3) voltage is charged to the output voltage when the freewheeling diode (D1) turns on. In this way, the sampling capacitor (C3) samples and holds the output voltage for output regulation. The sampling capacitor (C3) voltage decreases when the L1 inductor current falls below the output current. When the feedback voltage falls below the 2.55V reference voltage, a new switching cycle begins. Figure 4 shows this operation under CCM in detail.
Use the following equation to determine the output voltage:

\[ V_o = 2.55V \times \frac{R1 + R2}{R2} \]

**Frequency Foldback and Peak Current Compression**

The MP158 remains highly efficient under light-load condition by reducing the switching frequency and peak current automatically.

Under light-load or no-load conditions, the output voltage drops very slowly, which increases the MOSFET off time. Thus the switching frequency decreases as the load decreases.

Determine the switching frequency as:

\[ f_s = \frac{(V_{in} - V_o)}{2L(I_{peak} - I_o)} \cdot \frac{V_o}{V_{in}}, \text{ for CCM} \]

\[ f_s = \frac{2(V_{in} - V_o)}{L_1 I_{peak}^{2}} \cdot \frac{I_o}{V_{in}}, \text{ for DCM} \]

At the same time, the peak current limit decreases as the off-time increases. In standby mode, the frequency and the peak current are both minimized, allowing for a smaller dummy load. As a result, peak-current compression helps further reduce no-load consumption. Peak current limit can be estimated from the following equation (\( \tau_{off} \) is the MOSFET’s off time):

\[ I_{peak} = 101mA - (1mA / \mu s) \times (\tau_{off} - 9\mu s) \]

**EA Compensation**

MP158 has internal error amplifier and compensation loop. It samples the feedback voltage 6\( \mu \)s after the MOSFET turns off, and regulates the output based on the 2.55V reference voltage.

**Ramp Compensation**

An internal ramp compensation circuit improves the load regulation. As shown in Figure 5, an exponential signal added to pull down the reference voltage of the feedback comparator. The ramp compensation is a function of the load conditions: the compensation is about the 1mV/\( \mu \)s under full-load conditions compensation increases exponentially as the peak current decreases.

**Over-Load Protection (OLP)**

Maximum output power of MP158 is limited by maximum switching frequency and peak current limit. If the load current is too large, output voltage drops, so that the FB voltage drops.

When the FB voltage drops below 1.7V, it is considered as an error flag and timer starts. If the timer reaches 120ms (\( f_s=50kHz \)), OLP occurs. This timer duration avoids triggering OLP when the power supply starts up or load transition. The power supply should start up in less than 120ms (\( f_s=50kHz \)). The OLP delay time is calculated as per the following equation:

\[ \tau_{Delay} \approx 120ms \times \frac{50kHz}{f_s} \]

**Short-Circuit Protection (SCP)**

The MP158 monitors the peak current, and shuts down when the peak current rises above SCP threshold through short-circuit protection. The
power supply resumes operation with the removal of the fault.

**Thermal Shutdown (OTP)**

To prevent any thermal induced damage, the MP158 shuts down when the junction temperature exceeds 150°C. During the thermal shutdown (OTP), the VCC capacitor is discharged to 2.4V, and then the internal high voltage regulator re-charges. MP158 recovers when junction temperature drops below 120°C.

**Open-Loop Detection**

If $V_{FB}$ is less than 60mV, the IC stops switching and a re-start cycle begins. During Soft-Start, the open loop detection is blanked.

**Leading-Edge Blanking**

An internal leading-edge blanking (LEB) unit avoids premature switching pulse termination due to turn on spike. Turn on spike caused by parasitic capacitance and reverse recovery of freewheeling diode. During the blanking time, the current comparator is disabled and can not turn off the external MOSFET. Figure 6 shows the leading-edge blanking.

Topology Options
MP158 can be used in common topologies, such as Buck, Buck-Boost, Boost and Flyback, as illustrated in table 1.

Component Selection
Input Capacitor
The input capacitor supplies the DC input voltage for the converter. Figure 7 shows the typical DC bus voltage waveform of a half-wave rectifier.

![Input Voltage Waveform](image)

Freewheeling Diode
The diode should be selected based on maximum input voltage and peak current.

The freewheeling diode’s reverse recovery can affect efficiency and circuit operation under CCM, so use an ultra fast diode such as the EGC10JH.

Output Capacitor
The output capacitor is required to maintain the DC output voltage. Estimate the output voltage ripple as:

$$V_{CCM\_ripple} = \frac{\Delta i}{8f_s C_o} + \Delta i \cdot R_{ESR}, \text{ for CCM}$$

$$V_{DCM\_ripple} = \frac{l_o}{f_s C_o} \left( \frac{l_{pk} - l_o}{l_{pk}} \right)^2 + l_{pk} \cdot R_{ESR}, \text{ for DCM}$$

It is recommended to use ceramic, tantalum or low ESR electrolytic capacitors to reduce the output voltage ripple.

Feedback Resistors
The resistor divider determines the output voltage. Appropriate R1 and R2 values should be chosen to maintain $V_{FB}$ at 2.55V. R2 is typically 5kΩ to 10kΩ, avoid large R2 value.

Feedback Capacitor
The feedback capacitor provides a sample and hold function. Small capacitors result in poor regulation at light loads, and large capacitors affect the circuit operation. Roughly estimate an optimal capacitor value using the following equation:

$$\frac{1}{2 \frac{V_o}{R_1 + R_2} \cdot \frac{C_o}{l_o} \cdot \frac{C_{FB}}{l_o}} \leq C_{FB} \leq \frac{V_o}{R_1 + R_2} \cdot \frac{C_o}{l_o}$$

Dummy Load
A dummy load is required to maintain the load regulation. This ensures sufficient inductor energy to charge the sample and hold capacitor to detect the output voltage. Normally a 2mA dummy load is needed and can be adjusted according to the regulated voltage. The dummy load reduces the efficiency and increases the no-load consumption.

Typically, a half-wave rectifier requires an input capacitor rated at 3uF/W for the universal input condition. When using a full-wave rectifier, input capacitor is chosen as 1.5~2uF/W for the universal input condition. A minimum DC voltage below 70V should be avoided, since it may cause thermal issue.

Inductor
The MP158 has a minimum off-time limit that determines the maximum power output. The maximum power increases as the inductor increases. Using a very small inductor may cause failure at full load, but a larger inductor means a higher OLP load. It is recommended to select an inductor with the minimum value that can supply the rated power. Estimate the maximum power with:

$$P_{omax} = V_o \left( \frac{l_{peak}}{2} - \frac{V_o \cdot \tau_{min\_off}}{2L} \right), \text{ for CCM}$$

$$P_{omax} = \frac{1}{2} \frac{l_{peak}}{2} \cdot \frac{1}{\tau_{min\_off}}, \text{ for DCM}$$

For mass production, tolerance on the parameters, such as peak current limitation, minimal off time, should be taken into consideration.

To reduce costs, use a standard off-the-shelf inductor no less than the calculated value.
So, when reducing dummy load to achieve 30mW no load requirement, no load regulation will get worse.

Use a zener to reduce no-load consumption if no-load regulation is not a concern.

Auxiliary VCC Supply

For $V_O$ above 7V applications, MP158 can achieve the 30mW no-load power requirement. In order to do this, chip requires an external VCC supply to reduce overall power consumption.

This auxiliary VCC supply is derived from the resistor connected between C3 and C4. C4 should be set larger than recommendation above. D3 is used in case that VCC interfere with FB, R3 is determined per the formula below.

$$ R \approx \frac{V_O - 5.8V}{I_S} $$

Where $I_S$ is the VCC consumption under no load condition. R should be adjusted to meet the actual $I_S$, because it varies in different application. In a particular configuration, $I_S$ is measured as about 180μA.

Surge Performance

Select an appropriate input capacitor value to obtain a good surge performance. Figure 9 shows the half-wave rectifier. Table 2 shows the capacitance required under normal condition for different surge voltages. In this test, FR1 is 20Ω/2W fused resistor and L1 is 1mH.

Layout Guide

PCB layout is very important for reliable operation, good EMI and thermal performance. Please follow these guidelines to optimize performance.

1) Minimize the loop area formed by the input capacitor, IC, freewheeling diode, inductor and output capacitor.

2) Place the power inductor far away from the input filter while keeping the loop area to the inductor to a minimum, see example below.

3) Place a capacitor valued at several hundred pF between the FB pin and source as close the IC as possible.

4) Connect exposed pads or larger copper area with the DRAIN pin to improve thermal performance.
Design Example

Below is a design example following the application guidelines for the specifications:

<table>
<thead>
<tr>
